

# **Differences between perovskite cells and solar glass cells**

## Overview

---

Are perovskite solar cells a viable photovoltaic technology?

Perovskite solar cells (PSCs) have emerged as a viable photovoltaic technology, with significant improvements in power conversion efficiency (PCE) over the past decade. This review provides a comprehensive overview of the progress, challenges, and future prospects of PSCs.

How are perovskite solar cells made?

Perovskite solar cells can be manufactured using conventional n-i-p or p-i-n architecture, sandwiching the perovskite absorber layer between a Hole Transporting Layer (HTL) and an Electron Transporting Layer (ETL). The order of these layers varies with the architecture of the cell.

What are perovskite silicon tandem solar cells?

Perovskite silicon tandem solar cells are created by stacking a perovskite absorber layer (including HTL and ETL), on top of an n-type c-Si layer, featuring a recombination layer between them, made out of hydrogenated a-Si (a-Si:H) or nanocrystalline silicon (nc-Si).

What is the difference between crystalline silicon and perovskites?

Crystalline silicon is limited to absorbing wavelengths equal to or superior to 1,100 nm, while perovskites can be tuned to respond to a wider variety of colors in the solar spectrum. This feature can be exploited in the future, creating solar panels that convert most wavelengths in the solar spectrum.

## Differences between perovskite cells and solar glass cells
